**Guidelines for Psychological Practice with Women  
with Serious Mental Illness**

## Guidelines for Psychological Practice with Women with Serious Mental Illness

### Introduction

47  
48  
49  
50  
51  
52       Serious mental illness (SMI) refers to major mental health disorders that lead to  
53 serious impairment in at least one area of functioning, including social,  
54 academic/occupational, and daily living activities (Kessler et al., 2003; Substance Abuse  
55 and Mental Health Services Administration [SAMHSA], 2017). SMI typically includes  
56 bipolar disorder, schizophrenia spectrum disorders, severe depression, and posttraumatic  
57 stress disorder (PTSD). There are many challenges that individuals may undergo due to  
58 their experience of SMI, including the impact of stigma and marginalization. In fact, the  
59 experience of SMI may be as much about the experience of oppression through stigma  
60 and marginalization, as it is about symptoms of mental illness itself (Anthony, 1993). In  
61 particular, women who experience SMI are prone to experience other challenges such as  
62 trauma, homelessness, poverty, and single parenting (Jonikas et al., 2003; Mowbray et  
63 al., 2003). According to the National Association of Mental Illness (NAMI, 2017), recent  
64 prevalence data indicated higher rates of SMI for women (21.7%) than for men (14.5%).  
65 Additionally, the intersectionality of social minority identities for women with SMI can  
66 multiply their oppressive experiences through the combined effects of racism, sexism,  
67 ableism, classism, and mental illness stigma (APA Guidelines for Psychological Practice  
68 for People with Low-Income and Economic Marginalization, 2019; Carr, Greene, &  
69 Ponce, 2015; Mizock & Carr, 2016).

70       The mental health field has historically struggled with its oppression of women.  
71 Theories of gender differences have often reinforced a gender bias, as evidenced by the  
72 attribution of SMI to biology and the labeling of women as “mad” for not conforming to

73 gender norms (Gove, 1980; Mizock & Carr, 2016; Ussher, 2011). Even in more modern  
74 times there is evidence of discriminatory practices towards women in the mental health  
75 field, ranging from clinical bias, misdiagnosis, and mistreatment, (Eriksen & Kress, 2008;  
76 Mueser et al., 1998; Seeman, 2000; Usher, 2011). The general principles of the APA  
77 Code of Ethics (2002), the basic foundational principles that offer guidance for how  
78 psychologists are encouraged to aspire to the highest ethical ideals in the profession,  
79 include Principle D: Justice and Principle E: Respect for people's Rights and Dignity.  
80 These principles embody the ideals that all individuals are entitled to benefit from  
81 psychology and that there should be equitable process for them, including fairness and  
82 justice in the delivery of psychological services. Furthermore, psychologists shall respect  
83 the rights of people for self-determination and that there may need to be safeguards in  
84 place for the welfare of people that may be vulnerable, such as those who experience  
85 psychiatric disability. The APA Guidelines for Psychological Practice with Women and  
86 Girls have called attention to gendered oppression and the impact of such on mental  
87 health challenges in general (APA, 2018). This has been an important stride towards  
88 improved psychological practice with women and girls. However, guidelines for  
89 psychological practice are needed to address the specific, unique needs of women with  
90 SMI in particular, as there is a significant overarching guide for women with these  
91 concerns.

## 92 **Purpose**

93 The purpose of the *Guidelines for Psychological Practice with Women with*  
94 *Serious Mental Illness* is to aid psychologists in understanding aspirational tenets in  
95 providing clinical services to women with SMI. As seen in the literature (Jonikas et al.,

96 2003; Mowbray et al., 2003), women with SMI are likely to experience unique challenges  
97 and experiences, which has the capacity to inform the best methods of engagement in  
98 clinical practice. These practice guidelines can best direct professional behaviors and  
99 decisions of psychologists who work with women with SMI, as suggested by the criteria  
100 for practice guidelines set by the American Psychological Association (APA, 2015), and  
101 also provide a culturally responsive, trauma-informed approach to clinical engagement  
102 with a focus on offering both equity of access and equity of outcomes. Moreover, these  
103 guidelines strive to be informed by recovery-oriented care models. Recovery refers to not  
104 solely symptom elimination alone, but living a life of satisfaction, meaning, and self-  
105 determination in the face of a major mental health problem (SAMSHA, 2012).

#### 106 **Recovery**

107 The term “recovery” is a shift away from traditional uses of the word, such as the  
108 absence of symptoms or substance use, but focuses on hope, self-determination,  
109 empowerment, and person-centered care (SAMSHA, 2012). The recovery-oriented care  
110 movement originates with the consumer movement in the 1960s and 1970s in which  
111 individuals in hospitals fought for their rights and the capacity to live autonomously in  
112 the community and to have a life that was more than just being a patient (Davidson,  
113 Tondora, Lawless, O’Connell, & Rowe, 2009). The experience of those with mental  
114 illness, then, was as much about the sociopolitical experience of stigma, marginalization,  
115 and discrimination as it was about mental illness. We strive to use the term “recovery” to  
116 refer to this lifelong process and healing, which recognizes the additive experiences of  
117 illness or trauma but we want to note the fact that these are different in some way due to  
118 such a life-changing event. Some individuals living with SMI also indicate that, after and

119 within a process of recovery and healing, they feel as if they have evolved into an even  
120 better form of themselves or positively altering their identity, though recovery does not  
121 negate or erase the experiences they have had in their life.

## 122 **Documentation of Need**

123 There are many factors that reflect a need for the development of practice  
124 guidelines for women with SMI. The Committee on Professional Practice and Standards  
125 (COPPS) has specifically noted three categories that suggest a need for practice  
126 guidelines: (1) legal and regulatory issues, (2) public benefit, and (3) professional  
127 guidance (APA, 2015). We will address these categories and rationale for the  
128 development of the *Guidelines for Psychological Practice with Women with Serious*  
129 *Mental Illness*. We will move on to this next, in detail, and review it in relation to the  
130 legal and regulatory issues, ways in which these guidelines can benefit the public, and  
131 offer professional guidance.

132 As this relates to legal and regulatory issues, there are no distinct and clear  
133 guidelines on the impact of specific practices that are part of the provision of mental  
134 health services, such as use of voluntary and involuntary medications, seclusion and  
135 restraint, and the resulting impact on women with serious mental illness. It is vital that  
136 there is some guidance due to the supporting literature indicating disparate and unique  
137 experiences of women. As for public benefit, these guidelines offer support for enhancing  
138 the treatment and efficacy of working with women with serious mental illness, who are  
139 particularly prone to the intersectionality of oppressive experiences and who are at  
140 disparate risk for marginalization and stigma. With the development of these guidelines  
141 the recovery process of women with serious mental illness can be advanced and the field

142 can also gain traction, with the literature that continues to grow. It is of note that as  
143 psychologists begin to use these guidelines, or as future revisions of the guidelines are  
144 developed, there may be additional reasons that document the critical need to inform  
145 clinical practice with women with SMI.

#### 146 **Legal and Regulatory Issues**

147 APA indicates that where the legal and regulatory bodies are silent on assisting  
148 psychologists in recommended practices and there is a realized need due to the silence of  
149 these bodies, the development of guidelines may be enacted (APA, 2015). The notable  
150 gaps in the law and regulation of seclusion and restraints and its impact on those who  
151 experience such measures in the mental health system call for organizations and bodies,  
152 such as the APA, to help guide psychological practice. It is also important that though  
153 guidelines can help where there is silence by legal and regulatory bodies, the guidelines  
154 themselves do not supersede federal and state laws (APA, 2015).

155 Seclusion and restraints are still allowed in the United States in the delivery of  
156 psychiatric care despite the moral movement in the 1800s, which advocated for the  
157 elimination of this practice (American Psychiatric Nursing Association Position on the  
158 Use of Seclusion and Restraint, 2014). Many interested parties (National Association of  
159 Mental Illness [NAMI], National Association of State Mental Health Program Directors  
160 [NASMHPD], Substance Abuse and Mental Health Services Administration [SAMSHA])  
161 have advocated for the elimination or reduction of the use of seclusion and restraint due  
162 to the traumatizing and potentially lethal impact they can have on those who experience  
163 its parameters, including both clients and staff (Boner, Lowe, Rawcliffe, & Wellman,  
164 2002; Curie, 2005; Frueh et al., 2005; Glover, 2005; Mental Health America, 2015;

165 NAMI, 2001; Sailas & Fenton, 2001). In fact, SAMHSA has called for the federal  
166 government to develop a unified policy on the use of seclusion and restraint for those  
167 with mental illness (Curie, 2005). NAMI has developed guidelines for the protection of  
168 the rights of those with mental illness that include the right to protection from harm, least  
169 restrictive environments, and never subjecting individuals to seclusion and/or restraint  
170 unless it is absolutely necessary to prevent imminent or immediate harm from occurring  
171 to the individual or someone else (NAMI, 2001). Relatedly, the director of the  
172 NASMHPD has made it a priority to reduce seclusion and restraint in state mental health  
173 facilities and advocated for the ultimate elimination of such practices (Glover, 2005).  
174 Since the NASMHPD has made this a focus in many state facilities there has been a 16%  
175 reduction in the use of restraint and a 45% reduction in the use of seclusion in those  
176 targeted facilities (Glover, 2005; Mental Health America, 2015).

177         Though these nationally recognized efforts exist, there are no overriding federal  
178 mental health policies or laws that have banned the use of restraint and seclusion. The  
179 laws and/or policies that do dictate use of seclusion and restraint are silent on offering  
180 psychological practice that is trauma-informed and recovery-oriented, which may  
181 decrease the use of such traumatizing practices. However, SAMHSA, recently led a  
182 charge for reforming mental health care by integrating trauma-informed and recovery-  
183 oriented care in service delivery in order to reduce such punitive measures (SAMHSA,  
184 2010). Therefore, given the high likelihood for retraumatization of women with SMI in  
185 our systems of care from such methods as seclusion and restraint, and the already  
186 incredibly high rates of trauma for women with SMI (Frueh et al., 2005; Goodman et al.,  
187 2001; Sailas & Fenton, 2001), psychological practice guidelines can alert psychologists

188 to these dynamics and subsequently attempt to decrease likelihood of retraumatization.  
189 Relatedly, the American Psychological Association greatly values human rights, as  
190 evidenced by its code of ethics (APA, 2002) which indicates that the discipline of  
191 psychology, and the academic, clinical, and other professional activities can and are  
192 encouraged to serve as a mechanism for securing and advocating for human rights. Such  
193 an approach is imperative when working with women with SMI as this is consistent with  
194 the values and virtues of the APA ethics code to do no harm and protect the human rights  
195 and dignity of all people (APA, 2015). APA's strategic plan (APA, 2018), also embraces  
196 centrally the goal of human rights for all and its innovative strategic plan is currently the  
197 guide for its goals, objectives, and action items as a whole organization and field,  
198 delivering global impact. Similarly, the World Health Organization (2017) has a strong  
199 focus on human rights and a mission to underscore the importance of understanding the  
200 disparate experiences of women with mental illness across the globe, as the medical field  
201 and different countries embark upon mechanisms to reduce these inequities.

## 202 **Public Benefit**

203 As with other guidelines, these professional practice guidelines for women with  
204 SMI also benefit the public in various ways (APA, 2015). It is believed that these  
205 guidelines can improve service delivery by targeting a diverse population that  
206 experiences unique challenges and the intersectionality of oppressive experiences (Carr et  
207 al., 2015; Mowbray et al., 2003). Understanding these nuances and the implications of  
208 such experiences of women and thus how to provide psychological practice with women  
209 with SMI can only aid in the ability of psychologists to provide an effective and  
210 culturally responsive experience in our mental health systems. Without guidelines that

211 call attention to the unique experiences of women with SMI, this group may be  
212 overlooked in the conceptualization of how service delivery is provided and thus the  
213 impact on this group that has particular concerns may go unaddressed.

214 APA's report on the need for development of guidelines (APA, 2015) suggests  
215 that guidelines are needed when there is evidence that discrimination or bias can occur in  
216 the inappropriate treatment process of a group of individuals. As a result, practice  
217 guidelines can shed light on appropriate practice methods that would help avoid harm.  
218 Relatedly, the literature indicates that women frequently encounter discrimination and  
219 bias from mental health professionals, including in the overdiagnosis of specific disorders  
220 that are more stigmatizing, while often ignoring the role of trauma on symptom  
221 development (Archer, Lau, & Sethi, 2016; Eriksen & Kress, 2008; Mueser et al., 1998;  
222 Seeman, 2000; Usher, 2011). The guidelines for psychological practice with women with  
223 SMI call attention to a unique group of women, as their needs and unique concerns  
224 warrant further attention and understanding for appropriate engagement in the mental  
225 health field due to particularly disparate risk for marginalization and oppression.

226 These practice guidelines also serve the invaluable task of meeting the needs of an  
227 underserved and incredibly vulnerable population. As the literature indicates, women  
228 with SMI have to navigate the experience of gender oppression, which plays a role in the  
229 development and experience of SMI for women (Mizock & Carr, 2016). Additionally,  
230 women with SMI are more prone to trauma, homelessness, poverty, and stressors of  
231 single parenthood (Jonikas et al., 2003; Mowbray et al., 2003), not to mention the  
232 deleterious effects of the intersectionality of multiple oppressive experiences (Carr et al.,  
233 2015; Mizock & Carr, 2016). Conceptualization of all of these dynamics is crucial in

234 being able to offer psychological practice to women with SMI that is culturally  
235 responsive, ethical, trauma-informed, and recovery-oriented.

### 236 **Professional Guidance**

237 APA suggests that guidelines can also be developed to aid in new and diverse  
238 roles that psychologists fill in clinical practice or due to advances in theory and science  
239 (APA, 2015). The literature indicates that psychologists work in many diverse settings  
240 requiring organizational skills, as well as with individuals in public sector settings that  
241 treat people with complex concerns such as SMI (APA, 2009; Kohut, Li, & Wicherski,  
242 2007). Though psychologists are serving in the public sector, working with this specialty  
243 population, and serving in roles requisite of organizational skills, there is limited  
244 literature and training experiences on leadership, clinical skill development, or  
245 organizational development (APA, 2009; Reddy, Spaulding, Jansen, Menditto, & Pickett,  
246 2010). Moreover, many psychologists have not received specialized training in working  
247 with individuals with SMI, or women with SMI. Some groups are working on expanding  
248 the repertoire of training and specialization in the area of working with individuals with  
249 SMI such as Division 18 of APA, Psychologists in Public Service – Section on Serious  
250 Mental Illness/Severe Emotional Disturbance and the APA Task Force on Serious Mental  
251 Illness (APA, 2009; APA/CAPP Task Force on Serious Mental Illness and Severe  
252 Emotional Disturbance, 2007). Yet, there is a need for more guidance on the  
253 psychological practice with women with SMI.

254 There have been some advancements at APA in the psychological practice with  
255 individuals with SMI, including such documents as the *Proficiency in Psychology –*  
256 *Assessment and Treatment of Serious Mental Illness* (APA, 2009), the *Catalog of Clinical*

257 *Training Opportunities: Best Practices for Recovery and Improved Outcomes for People*  
258 *with Serious Mental Illness* (APA/CAPP Task Force on Serious Mental Illness and  
259 Severe Emotional Disturbance, 2007), and the *Recovery to Practice Curriculum*  
260 (American Psychological Association & Jansen, 2014). The new budding literature  
261 provides some evidence of the unique experiences of women with SMI and  
262 considerations for practice, but the development of these specific guidelines seeks to  
263 integrate the new literature and share that in a mechanism that can best inform  
264 psychological practice with women with SMI.

265         There has not been a specific, up-to-date, document that has addressed the unique  
266 needs of women and the role of sociocultural contexts in a manner that highlights the  
267 higher prevalence of SMI among women than their male counterparts, (NIMH, 2017). A  
268 greater focus on the cultural context of the experiences of women and the impact of  
269 trauma is needed to update the knowledge of providers as they work with women with  
270 SMI. These guidelines are especially important and critical given that women have  
271 disparate experiences and face intersecting oppressions from multiple levels when they  
272 also have an SMI, providing the impetus for the development of this document.

273         The scope of these guidelines includes some of the more disparate challenges that  
274 women with SMI face and the related challenges and intersectionality of experiences, as  
275 well as ways in which psychologists can be aware of these to better inform their modality  
276 of professional activities. Some issues beyond the scope of these guidelines, to name a  
277 few, include the unique challenges of men with SMI, the intersectionality of serious  
278 medical challenges, and biological and psychopharmacological considerations.

279 **Audience**

280 The intended audience for the *Guidelines for Psychological Practice with Women*  
281 *with Serious Mental Illness* includes psychologists, students, trainees, and experts that  
282 provide clinical care, engage in training and/or education, fill leadership positions in  
283 mental health organizations, and conduct research. There are many professional settings  
284 in which psychologists may work that are highly relevant including, but not limited to  
285 community mental health, the Veterans Health Administration, state psychiatric hospitals,  
286 private psychiatric hospitals, academic medical schools, graduate schools, counseling  
287 centers, and even in private practice. Given that 11% of women experience an SMI and  
288 SMI is higher among women than men, these guidelines have the potential to reach a  
289 considerable number of people in the general population that can benefit from such an  
290 addition to the field (National Institute of Mental Health, 2017; Substance Abuse and  
291 Mental Health Services Administration, 2003). Furthermore, an APA employment survey  
292 of 22,502 psychologists found 30% of psychologists practice in health care settings such  
293 as VA medical centers, community mental health centers, and general hospitals, which  
294 are settings where individuals with SMI engage in healthcare services (APA, 2009;  
295 Kohut, et al., 2007). Since there are so many psychologists in these settings it is  
296 important to be aware that psychologists are part of multi-disciplinary consultation and  
297 interprofessional collaborative teams, with the propensity to impact care within and  
298 across systems. Ultimately, this unique population is served in many settings, by  
299 psychologists and trainees with diverse career trajectories and, thus, there is substantial  
300 need for these guidelines.

### 301 **Guidelines and Standards**

302 It is important to clarify that guidelines are different than standards. In accordance  
303 with APA policy, guidelines are suggestions or recommended professional behavior  
304 and/or conduct for psychologists, whereas, standards are mandatory and can be enforced  
305 (APA, 2015). In essence, guidelines are not mandatory or exhaustive. Hence, these  
306 guidelines are written so that psychologists can strive to work towards aspirational goals  
307 of practice and are not meant to be mandatory, with the understanding that they may not  
308 pertain to all psychologists, dependent on their area of expertise and scope of practice.  
309 Guidelines are also developed to foster current advances in psychological practice.  
310 Similarly, guidelines do not take precedence over the professional judgments of  
311 psychologists founded on the knowledge base and scientific literature of the  
312 psychological field (APA, 2015).

### 313 **Trajectory of Guideline Development**

314 These guidelines developed as a product of the development of a Task Force on  
315 Women with Serious Mental Illness, which was developed in Division 35, the Society for  
316 the Psychology of Women of the American Psychological Association. The Task Force  
317 on Women with Serious Mental Illness was proposed in 2013 to the executive committee  
318 of Division 35 and accepted for development. Later, the Task Force became a committee  
319 and the guidelines originated as an action item from this working group. (For further  
320 history on the development of this task force then committee and the ensuing  
321 development of guidelines, see Appendix B.) As a result, this document contains 13  
322 guidelines for psychological practice with women with SMI. Each guideline includes a  
323 rationale section and application of the literature to psychological practice. It is noted that  
324 these guidelines apply to women from diverse sexual, gender, and other minority

325 identities, and can be integrated alongside other guidelines such as the APA Guidelines  
326 for Psychological Practice with: Transgender and Gender Nonconforming People; Girls  
327 and Women; Lesbian, Gay & Bisexual Clients and the Multicultural Guidelines. There  
328 was no financial support for the development of these guidelines and no conflicts of  
329 interest. The authors of the guidelines extensively reviewed the background literature  
330 relevant to each guideline and included major findings that were relevant to each topic.  
331 Supporting literature for each guideline was further evaluated and augmented in the  
332 integration of suggested revisions from content experts. These experts specialized in APA  
333 guideline development and psychological practice with women and people with SMI.

334 **Guideline expiration.** The expiration date of these guidelines is scheduled for 10  
335 years from their release, from the date by which they are approved by the Council of  
336 Representatives of APA. Therefore, these guidelines are to be reviewed and updated to  
337 reflect new literature and the development of the field.

### 338 **Practice Guidelines**

339 ***Guideline 1: Psychologists strive to provide recovery-oriented care to women with***  
340 ***serious mental illness that acknowledges their right to self-determination.***

341 **Rationale.** Gender is “a critical determinant of mental health and mental illness”  
342 (World Health Organization [WHO], 2017), influencing the differential power and  
343 control that women have in their lives. For example, the higher prevalence of sexual  
344 violence to which women are exposed and the subsequent trauma-related sequelae makes  
345 it imperative to address trauma in psychological care. In terms of professional biases,  
346 medical providers are more likely to diagnose depression in women compared to men  
347 (Nolen-Hoeksema, 2011), even when controlling for self-reported and presentation of

348 symptoms. According to a recent national survey, 23.8% of women compared to 15.6%  
349 of men have a mental illness (SAMHSA, 2009). Risk factors such as socioeconomic  
350 status, social position, and trauma exposure may lead to repeated experiences of  
351 disempowerment, domineering relationships, and differential health care in women with  
352 SMI.

353 Recovery began as a social justice movement in the 1960s and 1970s, led by  
354 consumers with SMI (Davidson et al., 2009). Across many eras and cultures, the  
355 prevailing professional model of responding to SMI has been the medical model, a  
356 patriarchal, pathologizing, and institutionalizing approach to working with individuals  
357 with SMI. More recently, recovery has begun to penetrate the field of psychology. As a  
358 result, SAMHSA has come up with an official definition of recovery: “A process of  
359 change through which individuals improve their health and wellness, live a self-directed  
360 life, and strive to reach their full potential” (2012). The four major dimensions that  
361 support a life in recovery are health (physical and emotional), home, purpose, and  
362 community. Moreover, recovery-oriented services are also guided by principles such as  
363 being respectful, being culturally responsive, addressing trauma, and involving strengths  
364 and responsibility of individual, family, and community.

365 **Application.** Providers are encouraged to provide recovery-oriented care to  
366 women with SMI. Again, the ten principles of recovery, as developed by SAMHSA, are  
367 useful tenets to use and guide the implementation of recovery-oriented care with women  
368 with SMI (SAMHSA, 2012). Those tenets of service delivery include, but are not limited  
369 to the following: providing hope, offering person-driven mental health services, holding  
370 respect for the individual, recognizing and amplifying strengths/responsibility, addressing

371 trauma, understanding and integrating the role of culture, providing a relational approach,  
372 offering peer support and holistic treatment, and understanding that recovery/healing  
373 occurs through many pathways. These goals for recovery-oriented care are guides for  
374 how psychologists can help provide services in a way that seeks to incorporate these  
375 tenets and abide by them as they seek to engage in the recovery process of the individual.

376 *Practice applications.* Analogously, from a recovery-oriented care perspective,  
377 person-first and non-stigmatizing language is encouraged (Titchkosky, 2001). One  
378 aspect of care which may require alteration is the traditional treatment plan. This is being  
379 replaced by the individualized recovery plan across major behavioral health care systems  
380 (Tondora, Miller, Slade, & Davidson, 2014). Individualized recovery plans are similar to  
381 person-centered care plans, which are becoming standard practice in health care across  
382 the globe (Tondora, Miller, Slade, & Davidson, 2014; Ekman, et al., 2011). Not only are  
383 individualized recovery plans strengths-based, personalized, and culturally-relevant, but  
384 they also continue to meet rigorous clinical documentation requirements by incorporating  
385 mental health and/or substance use issues that need to be addressed in recovery. Traits of  
386 recovery planning such as delineating the respective responsibilities of the consumer,  
387 provider, and her support network, focusing on the individual's personal goals and  
388 interests, and anticipating and preparing for a non-linear path of recovery, would  
389 communicate hope and strategies for a woman with SMI to overcome negative  
390 experiences of her illness, social position, and personal life history. The plan would also  
391 focus on the strengths and resilience of the individual as they seek community  
392 reintegration, recognizing this may occur via diverse pathways as each person seeks their  
393 own goals.

394            *Systems application.* Another aspect for psychologists to attend to is the context  
395 and environment in which women with SMI receive health care, and the gaps that may  
396 cause care to be rendered in an oppressive fashion. For example, inpatient psychiatry  
397 settings, which this population may present to, historically abide by the medical model,  
398 which may be characterized by: a problem focus, symptom reduction, medication  
399 compliance, and behavioral control (Slade, 2009). Health care provided within this  
400 framework is often incongruous to a recovery orientation, which, in contrast, promotes a  
401 holistic appraisal of the individual, believes in multiple mechanisms for a positive  
402 outcome, addresses trauma, and collaborates with the individual, family, and community  
403 (Davidson et al., 2009). Recovery also does not stop with symptom reduction but is a  
404 non-linear journey. Psychologists are encouraged to be aware of the role that they may  
405 play in facilitating feelings of personal safety with individuals (e.g., the orientation of  
406 office furniture and seating arrangement of parties). Furthermore, psychologists strive to  
407 recognize that they may bring to light the potentially harmful practices and policies that  
408 may undermine recovery. Examples of these include, but are not limited to: use of  
409 medications to control behavior, the side effects of medications, room sharing, use of  
410 seclusion and restraint, and the under-identification of traumatic stress, dual diagnoses,  
411 and co-morbid health problems (Frueh et al., 2005; Mueser et al., 1998; Davidson et al.,  
412 2009). Psychologists strive to identify and advocate alternative practices that promote  
413 recovery, such as respectful, collaborative provider-consumer communication, positive  
414 behavior supports (Hamlett, Carr, & Hillbrand, 2016), and adequate identification and  
415 intervention on relevant medical and mental health issues (Davidson et al., 2009).

416           **Training applications.** Recovery-oriented care may be incorporated into training  
417 and implementation of interventions such as brief education on trauma and self-  
418 management skill-building, while also recognizing the potential limitations of inpatient  
419 psychiatry (e.g., treatment duration, crisis stabilization). Additionally, all staff could be  
420 trained in trauma-informed care practices, from the support staff to clinical staff, as well  
421 as senior administration. It is important to understand the literature on the use of inpatient  
422 hospitalization and the efficacy for its use, while remaining aware of the costs and risks  
423 of longer-term hospitalization such as the risk of retraumatization and institutionalization  
424 (Frueh et al., 2005).

425           **Cultural applications.** Across various care settings, psychologists are encouraged  
426 to take care to infuse cultural responsiveness and self-determination into their work with  
427 women with SMI. A culturally responsive approach may often be overlooked in the  
428 service of women with SMI, despite the reality that it can be particularly valuable and  
429 beneficial (APA, 2017). A culturally responsive approach aims to not only be sensitive or  
430 aware but also be responsive to the element of culture and unique experience of the  
431 client. Literature on culturally responsive therapeutic relationships makes suggestions  
432 including, but not limited to, being culturally-informed but the provision of person-  
433 specific assessment of the presenting issue, exploring a person's perspective on seeking  
434 treatment and of the therapeutic relationship, and using technique-specific cultural  
435 modifications as appropriate (Asnaani & Hofmann, 2012).

436           Understanding the unique needs of women with SMI and providing an  
437 empowerment approach could potentially allow women to tap into their strengths and  
438 capabilities as they embark on their recovery journey. An empowerment orientation

439 allows individuals, families, and communities to gain influence over sociopolitical factors  
440 that affect their health and well-being (Worrell & Remer, 2003). This approach focuses  
441 on the strengths and resilience of the individual in their capacity and ability to deal with  
442 past, current, and future stress and trauma.

443 ***Community and advocacy applications.*** Psychologists are also encouraged to be  
444 advocates for approaches in mental health service delivery that strive to offer social  
445 justice-informed interventions and services, such as access to adequate and evidence-  
446 based mental health care, housing, employment opportunities, and financial resources  
447 (Carr, Bhagwat, Miller, & Ponce, 2014). Similarly, psychologists are urged to recognize  
448 the potential need for care coordination and the importance of being familiar with other  
449 social services and natural supports, which seek to support women with SMI in their  
450 recovery journey. Relatedly, psychologists are encouraged to consider the use of  
451 technology-based interventions and the use of smartphones, text messaging, mobile apps,  
452 social media, and digital therapies to help women with SMI engage in the services that  
453 would be supportive of their recovery (Naslund, Aschbrenner, & Bartels, 2016).

454 Furthermore, psychologists are reminded to be aware of the complex process,  
455 slow timeline, and costs of inciting and advocating for systems change. Psychologists are  
456 encouraged to practice their own self-care, support network, and burnout potential, as it  
457 applies to being a change agent or a minority opinion in a multidisciplinary setting that  
458 may be characterized by limited resources, overburdened providers, and rigid public laws  
459 or policies.

460 ***Research applications.*** Psychologists that engage in research related to the  
461 experiences of those with SMI are encouraged to unearth more of an understanding of the

462 unique and intersecting experiences of women with SMI. They are also encouraged to do  
463 so from a culturally-informed and feminist approach, which takes in to account the multi-  
464 layered and intersecting oppressive experiences of women with SMI that contribute to a  
465 more complex and sociopolitical experience of their mental illness. Relatedly, researchers  
466 are encouraged to take caution to use assessment tools and instruments, which are  
467 applicable to women, including diverse women, so that their experiences may be best  
468 understood and highlighted from an ethically judicious framework.

469 ***Guideline 2: Psychologists strive to be aware of gender norms, expectations, bias and***  
470 ***discrimination and how these factors impact women's mental health and sense of self-***  
471 ***worth.***

472 **Rationale.** Sexism impacts differences in the rates, development, and recovery  
473 from mental illness among women (Gove, 1980). Sexism and gender-based  
474 discrimination include imbalances in power and mistreatment related to gender, which  
475 occur in the form of stereotypes, attitudes, values, as well as interpersonal and  
476 institutional discrimination (Logie et al., 2011). As a result of sexism, women are held to  
477 gender ideals and expectations in the dominant culture to be subservient, dependent,  
478 noncompetitive, emotional, sensitive, thin, traditionally attractive, and focused on their  
479 appearance (Broverman et al., 1970; Erchull, 2015; Eriksen & Kress, 1970). When  
480 women do not conform to these gender expectations, they may be judged harshly by  
481 peers, family members, partners, providers, and others in their social network, adding to  
482 mental distress (Angermeyer, Matschinger, & Holszinger, 1998; Chrisler, 2012). From an  
483 early age, girls are socialized to direct their mental distress inward, resulting in a higher

484 expression of internalizing disorders such as depression, anxiety, and eating disorders  
485 (APA, 2018).

486 Women face daily experiences with sexism in a number of ways that add mental  
487 distress and worsen their mental health. These experiences with sexism tend to include  
488 stereotypic gender role expectations, rigid beauty ideals, disproportionate domestic labor  
489 responsibilities, barriers to attainment in education and employment, inequality in wages,  
490 higher rates of poverty, workplace stress due to sexism, imbalances in power in the  
491 family, as well as associated vulnerability to violence and sexual maltreatment (Buchanan  
492 & Fitzgerald, 2008; Carmen et al., 1981; Erchull, 2015; Eriksen & Kress, 2008;  
493 Sanderson & Thompson, 2002; Yoder, 2007). It has even been argued that the frequent  
494 experiences with sexism constitute a traumatic stress that increases the risk of poor  
495 workplace outcomes, psychological challenges, and the development of mental illness  
496 (Brown, 2000; Buchanan & Fitzgerald, 2008; Saunders, Scaturro, Guarino, & Kelly,  
497 2017).

498 **Application.** It is important that psychologists are mindful of the impact of  
499 sexism, as well as other forms of oppression, on the experiences of women with SMI.  
500 Psychologists strive to raise women's awareness of the impact of the sociocultural  
501 context on the lives and mental health of these women. Increasing women's awareness of  
502 oppressive gender-role messages and of institutionalized sexism empowers them by  
503 reducing self-blame and increasing awareness of stigma. Psychologists strive to conduct  
504 gender-sensitive assessments that investigate the impact of sexism, rigid gender roles,  
505 and traditional gender socialization on women's mental health (Archer, Lau, & Sethi,  
506 2015; Brown, 1990). Psychologists may help women target the sources of sexist

507 mistreatment through the involvement of family members in their mental health services  
508 (Eriksen & Kress, 2008), membership in women's empowerment groups, or connections  
509 to other resources in their community. Psychologists strive to support women with SMI  
510 to connect to these social supports and resources in order to bolster access to services,  
511 educational attainment, financial empowerment, and safety in order to reduce distress  
512 posed by inequities and sexism on their lives.

513 ***Guideline 3: Psychologists are encouraged to consider the intersectionality of identities***  
514 ***among women with serious mental illness including, but not limited to, gender, race,***  
515 ***ethnicity, class, sexuality, ability, and other identities in how they uniquely impact their***  
516 ***experiences with serious mental illness.***

517 **Rationale.** Intersectionality is important to culturally responsive psychotherapy  
518 and a vital issue for psychologists in promoting social change (Brown, 2009; Shields,  
519 2008). Intersectionality theory may capture more accurately the intersecting experiences  
520 of marginalization and privilege across different social identities among women with  
521 SMI. Intersectionality (Crenshaw, 1993) is a theory that may enhance understanding how  
522 various social identities among women with SMI contributes to compounded levels of  
523 stigma, oppression, and privilege. Intersectionality demonstrates how constructs like race  
524 and class are not separate processes but intersecting social hierarchies that determine  
525 access to power (Collins, 2000) and may impact mental health (Lewis, Williams,  
526 Peppers, & Gadson, 2017). For example, instead of just focusing on issues of race for an  
527 Asian American woman with an SMI, we would take into account her identity as an  
528 Asian American, lesbian, upper class woman with an SMI.

529 Similarly, intersectional stigma refers to the overlapping, multiple levels of stigma  
530 and discrimination faced by women with SMI from diverse backgrounds with regard to  
531 race, ethnicity, immigration, disability, sexual orientation, and other social identities  
532 (Logie, James, Tharao, & Loutfy, 2011). Women with SMI may be confronted not only  
533 with the stigma of mental illness, but also sexism, racism, classism, ableism, or  
534 homophobia. These multiple aspects of stigma may pose added barriers and stressors to  
535 the lives of these women with SMI.

536 **Application.** Psychologists take into account the impact of double stigma or  
537 intersectionality of mental illness stigma and sexism or another area of oppression on  
538 women's sense of self, relationships, access to basic needs, community integration, and  
539 mental health experience. Psychologists are encouraged to facilitate treatment options  
540 that strive to reduce internalized stigma and help women realize that their experience is  
541 fraught with a sociopolitical context, rather than seen singularly through a pathological  
542 lens, where the problem is thought to only reside within the person (Worrell & Remer,  
543 2003). Psychologists seek to inquire about the impact of intersectional oppression on  
544 women with SMI, and learn of any mistreatment in mental health services or otherwise  
545 that might add to multiple levels of stigma and affect the therapeutic alliance.

546 Psychologists strive to explore community resources and opportunities that might  
547 enhance awareness of these aspects of intersectional oppression in the lives of these  
548 women, and provide resources for overcoming the effects of multiple experiences with  
549 stigma. For example, psychologists aspire to support women with mental illness in  
550 gaining agency and helping others by becoming advocates to their peers. Psychologists

551 may be agents of social change in raising awareness of the impact of oppression on the  
552 lives of women with mental illness.

553           There are subgroups of women with SMI, i.e., special populations, to  
554 consider using an intersectional lens. For example, there are women with SMI who  
555 interface with the criminal justice system, and have unique concerns in psychological  
556 practice. Women with SMI in the criminal justice system tend to report higher rates of  
557 trauma, more extensive histories in the criminal justice system, and higher risks of  
558 problems with substance use, assault, running away, as well as crimes related to drug  
559 dealing and property offenses (Lynch, DeHart, Belknap, & Green, 2012). Other special  
560 populations include immigrant and refugee women with SMI, who may develop the onset  
561 or worsened symptoms of SMI, as a result of trauma and stress in the migration process  
562 (Donnelly, Hwang, Este, Ewashen, Adair, & Clinton, 2011). Hence, we must take into  
563 account the unique needs of other special populations of women with SMI and inquire  
564 and understand the impact of these intersecting identities on their mental health needs.

565 ***Guideline 4: Psychologists are mindful of the history of professional bias and stigma***  
566 ***that has been directed towards women with serious mental illness and reduced their***  
567 ***social power.***

568           **Rationale.** Historically there has been a challenging history in the psychiatric  
569 field with evidence of professional bias and stigma towards women (Archer, Lau, &  
570 Sethi, 2015; Eriksen & Kress, 2008; Reich, Nduaguba, & Yates, 1988; Seeman, 2000),  
571 and particularly women with SMI. Such experiences have marginalized women and  
572 disempowered them, reducing their social power and denying their right for respect,  
573 autonomy, and self-determination. This has been demonstrated in many ways though

574 some of the most apparent are in terms of disparities in the diagnosis and treatment of  
575 mental disorders (Eriksen & Kress, 2008; Reich, Nduaguba, & Yates, 1988; Seeman,  
576 2000). Among medical providers, women are more likely to be diagnosed with many  
577 mental disorders than men, even when self-report and presentation of symptoms are  
578 controlled for in studies. Interestingly, female gender is also a significant predictor of  
579 being prescribed a psychotropic medication for mood (WHO, 2017).

580 Professional biases propagated during undergraduate training, graduate training,  
581 and clinical training may include assumptions, from a medical model, that psychologists  
582 are better suited to working with clients without serious mental illnesses, because of the  
583 nature of psychotherapy (Furnham & Bower, 1992). In addition, there are some biases  
584 that individuals with serious mental illness may not benefit from psychotherapy. This  
585 seems to reveal a stigma against SMI, despite the independence between having a SMI  
586 and having the insight, motivation, and/or skills to benefit from psychosocial  
587 interventions. Ironically, direct care psychologists are scarcely represented in public  
588 sector health systems, where individuals with SMI are most likely to receive services  
589 (Mueser, Silverstein, & Farkas, 2013).

590 **Application.** Psychologists are encouraged to be aware of the historical bases of  
591 bias towards women in the field of psychiatry and engage in their own process of  
592 intrapersonal examination of any such conscious and unconscious biases they experience,  
593 which may impact diagnosis, treatment, or ideas regarding capacity for recovery. As  
594 psychologists engage in this reflection process, they are also encouraged to seek out  
595 consultation or peer supervision with other psychologists to empower their own capacity  
596 to work with women with SMI from a culturally responsive and mindful model.

597 Psychologists are also urged to consider infusing their approach to working with women  
598 with SMI with a feminist theoretical orientation. On the other hand, some psychologists  
599 may work in settings whose practices and culture may run counter to a feminist approach  
600 of empowering clients with self-determination and attempting to disrupt the assumption  
601 that the client is “less than” the clinician. In such cases, psychologists are encouraged to  
602 play an active role in transforming mental health care and find mechanisms to bring  
603 recovery-oriented values to organizations that have hierarchical models. This may be  
604 achieved by using literature to support such shifts in care and by emphasizing the value  
605 of such approaches, which are more respectful and person-centered, as well as by  
606 highlighting the potential for better outcomes (Davidson et al., 2009). Along these lines,  
607 the training of psychologists could be revised to include more empirical and inclusive  
608 representations of SMI in coursework and clinical work, which may impact the level of  
609 stigma among providers. Training programs are also encouraged to put more emphasis in  
610 their overall training on clinical work with those with SMI, as well as the unique needs of  
611 women with SMI, which could increase the representation of psychologists in the public  
612 sector, where many with SMI are receiving services. Lastly, training programs are  
613 encouraged to evaluate their programs for discriminatory biases based on gender and  
614 SMI, as there are some programs that do not integrate psychotherapy into the treatment  
615 model, and may not provide adequate training and education in these specialty areas,  
616 causing more bias in the field.

617 ***Guideline 5: Psychologists endeavor to exercise diagnostic caution given that***  
618 ***historically women have been disproportionately assigned diagnoses that incur greater***  
619 ***stigma or pathologize gendered approaches to coping.***

620           **Rationale.** There are known gender differences in the occurrence of mental  
621 disorders, including women’s increased rates of depressive, anxiety, and eating disorders  
622 (Nolen-Hoeksema, 2001). Gender differences have also been found in diagnostic  
623 practices, with women often being negatively judged by mental health providers when  
624 not conforming to gender stereotypes (Eriksen & Kress, 2008). There is a profound  
625 history of labeling women as “mad” when not in compliance with gender stereotypic  
626 behavior (Ussher, 2001). Research on contemporary mental health practice has continued  
627 to find gender bias among diagnosticians, including overdiagnosis of affective and  
628 personality disorders and underdiagnosis of substance use problems (Eriksen & Kress,  
629 2008; Seeman, 2000).

630           Women with SMI also are at greater risk of certain traumatic events, such as  
631 sexual abuse (Mueser et al., 1998), however, this is rarely diagnosed as PTSD or treated  
632 within psychiatric settings (Mueser et al., 2002). Furthermore, when such experiences of  
633 trauma present among women with borderline personality disorder (literature indicates as  
634 many as 86% of women with borderline personality disorder have experiences of  
635 childhood sexual trauma; Bryer et al., 1987), the trauma frequently goes untreated due to  
636 concerns for behaviors (Harned, 2013). Instead they may be met with disdain and  
637 resistance by providers as the clients’ interpersonal styles may understandably be  
638 untrusting and complex, given their constellation of traumatic experiences. Ironically,  
639 this may set up a vicious cycle within mental health systems that resemble experiences of  
640 victim blame. This cycle may also impair and negatively bias the treatment that is  
641 provided in systems of care.

642 Clinicians tend to assign characterological diagnoses that stigmatize women's  
643 gender socialization of emotional expression, as well as the consequences of their  
644 elevated rates of trauma. This includes the overdiagnosis of histrionic, borderline, and  
645 dependent personality disorders among women (Eriksen & Kress, 2008; Reich,  
646 Nduaguba, & Yates, 1988). Such experiences are also frequently quite stigmatizing and  
647 may be an indication to providers that this person is seen as "untreatable" (Eriksen &  
648 Kress, 2008; Reich, Nduaguba, & Yates, 1988).

649 Even the term, *serious mental illness* raises challenges for many psychologists  
650 who are concerned with medical model language that might locate the pathology within  
651 the woman rather than the dominant culture in which she encounters gender bias that  
652 contributes to her mental distress. This quandary poses a *diagnostic dialectical tension*  
653 (Mizock & Kaschak, 2015), where psychologists must balance avoidance of stigma with  
654 the power of naming a mental health problem to enable awareness, communication, and  
655 quality and appropriate treatment.

656 **Application.** Psychologists may experience tension in assigning pathological  
657 diagnoses to women with mental illness due to diagnostic stigma and the history of  
658 labeling women as mad (Ussher, 2011). Psychologists strive to work with clients in a  
659 collaborative manner to find names for the problem in order to reduce power differentials  
660 in diagnosis and enhance empowerment in the diagnostic process. Relatedly, they may  
661 offer an egalitarian approach to psychotherapy so as to increase self-efficacy, enhance  
662 and embolden capabilities, and reduce oppressive experiences in mental health systems.  
663 Psychologists are urged to perform gender-sensitive diagnostic evaluations that maintain  
664 awareness of the history of gender bias in this area and other forms of bias. Psychologists

665 are encouraged to take into account the experiences of sexism on the development of a  
666 mental health disorder in their assessments to reduce gender bias in diagnostic practice,  
667 including incorporation of assessment of trauma, as trauma is strongly associated with  
668 SMI (Moradi & Huang, 2008; Mueser et al., 1998). It is important to note that it is  
669 valuable to be person-centered in each of these encounters and to use sound professional  
670 judgment in realizing these applications.

671 ***Guideline 6: Psychologists endeavor to employ trauma-informed practice and***  
672 ***assessment of past or ongoing trauma in the lives of women with serious mental illness***  
673 ***given their vulnerability to abuse.***

674 **Rationale.** Women with SMI have a high likelihood of a history of trauma, with  
675 some statistics estimating that as many as 51-97% have a physical and/or sexual assault  
676 history (Goodman et al., 2001). Women in general experience high rates of physical and  
677 sexual violence and abuse (Chandy, Blum, & Resnick, 1996). Women who have  
678 encountered trauma are also at increased risk of developing a mental health problem  
679 (Herman, 1997; Jennings, 2009). Moreover, individuals with SMI have an elevated  
680 prevalence of trauma in general. According to a study by Mueser and colleagues (1998),  
681 98% of individuals with SMI reported exposure to at least one traumatic event, and 43%  
682 met criteria for PTSD as result of trauma. In addition, the first episode of psychosis may  
683 be traumatic in nature in itself, and has been found to rise to the threshold of diagnosable  
684 PTSD (Mueser & Rosenberg, 2003).

685 Traumatized women as well as women with a SMI are vulnerable to  
686 retraumatization (Goodman et al., 2001; Herman, 1997). Retraumatization frequently  
687 occurs in care settings in which a new incident stirs up the original trauma (Jennings,

688 2009). These multiple exposures increase the duration, frequency, and intensity of  
689 distress reactions (Duckworth & Follette, 2012). The triggering incident might resemble  
690 the original trauma in terms of content or interpersonal dynamics (Jennings, 2009). The  
691 psychologist and woman might be unaware of the retraumatization response as it occurs,  
692 and potentially aggravate the symptoms or retraumatize the woman again.

693         Retraumatization may also occur on an inpatient unit or other residential  
694 treatment facility, referred to as sanctuary trauma (Mueser et al., 1998). People with SMI  
695 are likely to be hospitalized and vulnerable to violence, abuse, coercion, and force in  
696 these settings. One study found that among participants with SMI, 8% had been sexually  
697 assaulted in a treatment facility, 31% had been physically assaulted, and 63% had  
698 witnessed a trauma (Frueh et al, 2005). Sanctuary trauma is so common that it has been  
699 proposed that healing from its effects is central to the recovery process (Anthony, 1993).

700         **Application.** Women with SMI are at risk of trauma, both as individuals with  
701 SMI and as women. These women are uniquely vulnerable to sanctuary trauma as well,  
702 and may have histories of multiple traumas in mental health settings that may serve as  
703 barriers to care. Psychologists are encouraged to ensure their competence in treatment  
704 and communicate their experience to their clients to instill a sense of safety. Also,  
705 psychologists are reminded to use professional judgment as they navigate the complexity  
706 of addressing the results of trauma and the way it manifests. Psychologists are urged to be  
707 aware of the factors that mask symptoms of trauma or block access to help. Psychologists  
708 are encouraged to be aware of culturally responsive assessments for trauma experiences,  
709 which may be utilized. An empowerment-oriented approach to clinical work with women  
710 with SMI may enhance effective treatment and reduce retraumatization in mental health

711 care. The excessive use of force and restraints in mental health settings may traumatize  
712 and retraumatize women with SMI. Psychologists are encouraged to implement policies  
713 in their organizations to avoid retraumatization of women in mental health settings given  
714 the history of sanctuary trauma and vulnerability to retraumatization while receiving  
715 services.

716 ***Guideline 7: Psychologists strive to investigate and address the effects of sexual abuse,***  
717 ***assault, and exploitation among women with serious mental illness.***

718 **Rationale.** Sexual trauma appears to be a particular risk for women with SMI  
719 compared to their male counterparts. According to one study, 56% of chronically  
720 hospitalized women with psychosis had a history of childhood incest (Lipschitz et al.,  
721 1996). Another study found a rate of 55% of women receiving outpatient mental health  
722 services reported a history of childhood sexual abuse compared to 18% of men (Belk &  
723 van der Kolk, 1987). A third study found 53% of women who had been in an inpatient  
724 psychiatric inpatient unit reported a history of physical or sexual abuse compared to 23%  
725 of male participants (Carmen, Rieker, & Mills, 1987). Mueser and colleagues (1998)  
726 found that among a study of men and women with SMI, 26% of men reported sexual  
727 assault during their lifetime, whereas 64% of women reported sexual assault. Inherently,  
728 there is striking evidence that sexual abuse, assault, and exploitation among women with  
729 SMI is a serious health concern. In fact, sexual trauma may be a key contributing factor  
730 to the development of SMI (Belk & van der Kolk, 1987; Lipschitz et al., 1996).

731 A study that reviewed traumatic or harmful experiences in psychiatric settings  
732 revealed exposure to sexual exploitation may even happen within inpatient settings  
733 among individuals with SMI (Frueh et al., 2005), which calls attention to the need for

734 understanding this risk and putting into place measures that strive to ensure the safety of  
735 women with SMI in such settings. Obviously, our systems of care are meant to be places  
736 of safety and geared towards aiding people in their journey towards well-being; if the  
737 very places they are going for treatment actually are more harmful, this presents a serious  
738 concern.

739 Thus, there is overwhelming evidence for concern regarding the prevalence of  
740 experiences of sexual exploitation among women with SMI and additionally this is of  
741 even greater concern as we recognize that the literature highlights that there is also a high  
742 prevalence of posttraumatic stress disorder (PTSD) among people with SMI, compared to  
743 the general population (Mueser et al., 2002). Inherently, this has implications for  
744 understanding the potential consequences of sexual trauma among women with SMI. A  
745 review of studies indicates that between 29-43% of individuals with SMI experience  
746 PTSD, however, fewer than 5% of individuals have a PTSD diagnosis reflected in their  
747 chart (Mueser et al., 2002).

748 **Application.** Psychologists are encouraged to inquire and offer screenings for  
749 victimization among women with SMI generally, as well as about lifetime abuse,  
750 childhood abuse, and recent abuse (Goodman et al., 2001). Additionally, the value of  
751 doing so among women with childhood abuse histories, frequent psychiatric  
752 hospitalizations, experiences of homelessness, or substance use histories is essential, as  
753 the literature shows these factors predict recent victimization (Goodman et al., 2001).  
754 Similarly, intake assessments and regular ongoing assessments ideally explore specific  
755 and behaviorally anchored questions about coercive sexual experiences, assaults, and  
756 threats, helping highlight any concerns about safety (Goodman et al., 2001).

757           Given the high likelihood that significant trauma-related symptoms may go  
758 unrecognized or overlooked in the diagnosis or treatment of PTSD (Mueser et al., 2002)  
759 among women with SMI, psychologists are encouraged to carefully evaluate for PTSD  
760 and integrate this knowledge into treatment planning, clinical decision making, and  
761 choice of treatment interventions. Additionally, in light of the potential for women with  
762 SMI to experience even more sexual traumatization in psychiatric settings, psychologists  
763 who are in leadership positions are encouraged to bring to the forefront such concerns to  
764 administrators, supervisors, and clinicians (Frueh et al., 2005). Furthermore,  
765 psychologists are encouraged to create dialogues and enter into discussions about  
766 procedures, policies, and training efforts that aspire to ensure further sexual exploitation  
767 does not occur in our systems of care, affording us the ability to offer care that is humane  
768 and safe (Frueh et al., 2005).

769           In considering treatment options for experiences of sexual exploitation among  
770 women with SMI, and specifically schizophrenia, psychologists are encouraged to think  
771 judiciously, using clinical judgment and consultation as needed, about the best  
772 intervention given the client's experiences with psychiatric symptoms. For example, the  
773 literature lacks clarity about whether exposure-based trauma treatment interventions are  
774 the best treatment for women with schizophrenia, as some women might experience  
775 retelling/recalling disturbing memories as highly distressing, which could lead to  
776 challenges with their psychiatric symptoms or symptom relapse (Goodman et al., 1997).  
777 Furthermore, many of the research studies exclude the experience of psychosis from  
778 treatment research studies so the evidence is not clear if such exposure-based treatments  
779 for sexual trauma are efficacious for women with schizophrenia. Researchers indicate

780 that some women with schizophrenia may benefit from a more gradual form of exposure-  
781 based treatment or a social-learning approach to treatment (Frueh et al., 1995; Penn &  
782 Mueser, 1996). Relatedly, a social skills training model that addresses interpersonal skills  
783 (social perception and labeling, self-assertion, self-protection, self-expression, relational  
784 mutuality), intrapersonal skills (self-soothing, self-esteem, self-trust, self-knowledge),  
785 and global skills (initiative taking, problem solving, identity formation) may be  
786 particularly helpful for women with SMI that have been sexually victimized (Harris,  
787 1996, 1997; Goodman et al., 1997; Harris & FalLOT, 1996). For those women who have  
788 self-injurious behavior and PTSD, a combination of DBT and prolonged exposure has  
789 been shown to be more beneficial than DBT alone, though this has not been researched  
790 among women with schizophrenia (Harned, Korslund, & Linehan, 2014). It is also worth  
791 noting that many well-known trauma treatments overlook the cultural and sociopolitical  
792 experiences context of trauma experienced by women of color or women with  
793 disabilities. Instead, many randomized clinical trials overlook these factors in the  
794 therapist and client, rather than examining whether the treatment specifically works for a  
795 woman of color with SMI and a physical disability (Goodheart, Kazdin, & Sternberg,  
796 2006).

797 ***Guideline 8: Psychologists are encouraged to be mindful of the financial wellness of***  
798 ***women with serious mental illness given that they are at higher risk of poverty, such***  
799 ***as,, when possible, facilitating access to adequate resources including supported***  
800 ***employment, housing, and education.***

801 **Rationale.** Poverty means not having sufficient resources to support oneself, and  
802 has far-reaching implications for the capacity to meet basic needs and participate in

803 educational, social, leisure, and community activities (Perese, 2007; Wilton, 2004). There  
804 is a multitude of evidence that poverty is associated with the experience of having an  
805 SMI, creating barriers for recovery (Deegan, 1993; Hudson, 2005; Perese, 2007). The  
806 greater degree of poverty among individuals with SMI contributes to the greater number  
807 of unmet needs, and more unmet needs are associated with a poorer quality of life and  
808 poorer health (Wiersma, 2006). In fact, SMI has been shown to be associated with \$193.2  
809 billion dollars' worth in reduction in personal earnings for one year in the U.S. (Kessler  
810 et al., 2008). Beyond that, there is also evidence that women with SMI may experience  
811 poverty at a more disparate level than men with SMI, with one study indicating men with  
812 SMI have an average of earnings of \$26,435 over a 12-month period and women with  
813 SMI earning an average of only \$9,302 over a 12-month period, among individuals that  
814 had some type of earnings to evaluate (Kessler et al., 2008). This study also indicated that  
815 SMI significantly predicts reduced earnings in comparison to other psychological  
816 disorders, which do not share the same prediction.

817 Employment, interestingly, is also associated with a better prognosis among those  
818 with SMI, but the literature indicates the employment rate is poor among this group  
819 (Draine, Salzer, Culhane, & Hadley, 2002; Strauss & Carpenter, 1981). Furthermore, the  
820 lifetime work experiences of individuals with SMI is limited (Draine, Salzer, Culhane, &  
821 Hadley, 2002). Successful employment is also linked with educational level, but  
822 educational level may be interrupted or mitigated by the experience of SMI or associated  
823 other social barriers (Blank, 1995; Draine, Salzer, Culhane, & Hadley, 2002; Kessler et  
824 al., 1995). Interestingly, although one third of illness-related days out of work in the U.S.  
825 is related to mental disorders rather than physical illness, less attention and support is

826 given to the experience of mental illness (Merikangas et al., 2007). The extent of poverty  
827 may be demonstrated by findings that those individuals with SMI who are on a monthly  
828 Social Security Income check may only have approximately \$120.00 left to cover  
829 personal items or recreational purchases after paying basic bills (Perese, 2007; Wilton,  
830 2004).

831 Poverty contributes to the social issue of homelessness among individuals with  
832 SMI, with the literature indicating between one-fourth to one-third of all homeless  
833 individuals experiencing an SMI (Fischer & Breakey, 1991; Folsom & Jeste, 2002;  
834 Sullivan, Burnam, Koegel, & Holenberg, 2000). Individuals from some racial/ethnic  
835 groups are at even higher risk of homelessness, as evidenced by the literature indicating a  
836 higher risk of homelessness among African Americans (Caton et al., 1994; Caton et al.,  
837 1995). Additionally, being homeless and having an SMI is associated with poorer quality  
838 of life, increased risk of victimization, poorer access to health services but higher mental  
839 health treatment costs, a greater likelihood of inpatient psychiatric hospitalization versus  
840 outpatient treatment, and less capacity to make mental health needs a priority over the  
841 need to take care of primary survival needs (Folsom et al., 2005; Gelberg, Gallagher,  
842 Andersen, & Koegel, 1997; Hibbs et al., 1994; Lehman, Kernan, DeForge, & Dixon,  
843 1995; North & Smith, 1992; Padgett, Struening, & Andrews, 1990; Rosenheck & Dennis,  
844 2001; Rosenheck & Seibyl, 1998; Wenzel, Koegel, & Gelberg, 2000).

845 The risk or dangerousness of being homeless is well demonstrated in the  
846 literature. Findings from a large study of homeless individuals with SMI found that 44%  
847 of individuals had experienced violent victimization within the previous two months  
848 (Choe, Teplin, & Abram, 2008; Lam & Rosenheck, 1998). Furthermore, the impact of

849 poverty and the experience of homelessness is particularly difficult for women; the  
850 literature shows that one-third of women with SMI who are episodically homeless have  
851 been physically or sexually assaulted within the prior thirty days, and recent victimization  
852 is associated with increased symptom severity presentation (Goodman, Dutton, & Harris,  
853 1997). As the authors of the Recovery to Practice Curriculum indicate (APA & Jansen,  
854 2014) homeless women are more vulnerable than homeless men and they may have  
855 children they are trying to care for while facing the dangers of homelessness.

856         **Application.** Women with SMI face greater poverty than men with SMI, raising  
857 significant implications for how psychologists think about engaging women in mental  
858 health treatment and how we conceptualize their experience with poverty. Psychologists  
859 are encouraged to start with striving towards cultural awareness and competence by  
860 developing their own knowledge related to the social experience of poverty and its  
861 impact on well-being among women with SMI. Calling on Sue, Ivey, and Pederson's  
862 (1996) well-known model for engaging in cultural competence, also adopted by the  
863 *Multicultural Guidelines* (APA, 2017; Sue, 2006), psychologists are urged to strive to  
864 understand the experience of poverty by women with SMI by understanding their own  
865 personal biases or values of poverty. Engaging in personal reflection regarding biases or  
866 values and how that may impact their understanding and engagement with a client is  
867 fundamental for engaging in cultural awareness. Psychologists are encouraged to make  
868 efforts to increase their own knowledge of the client's experience of poverty, which  
869 intersects with other experiences, and work at having appropriate cultural skills to work  
870 with the client in a manner that is respectful of being culturally sensitive to the  
871 experience of poverty and its intersectionality.

872 As psychologists engage in working towards cultural competence with  
873 understanding poverty and its implications for women with SMI, they are encouraged to  
874 do so in a manner that is consistent with the use of scientific mindedness, culture-specific  
875 skills, and dynamic sizing (Sue, 1998). In this respect, psychologists aspire to avoid  
876 making conclusions or assumptions without data about the impact of poverty on a woman  
877 with SMI (Sue, 1998; Sue, 2006). To expand on the concept of dynamic sizing,  
878 psychologists are urged to individualize and generalize a client's concerns in the  
879 treatment process based on person-specific information, as the psychologist explores the  
880 intersection of the client's various cultural contexts and multiple identities (Ridley, Hill,  
881 Thompson, & Omerod, 2001; Roysircar, Dobbins, & Malloy, 2009; Sue 1998).  
882 Psychologists may integrate the use of dynamic sizing by understanding when to  
883 generalize and when to individualize the knowledge base on women's experience of SMI  
884 and poverty, which helps with problems that may occur by stereotyping. Without such a  
885 foundation, psychologists may fail to understand the experience of a woman facing  
886 poverty and how that may impact her mental health, recovery, and psychotherapy.

887 Psychologists are encouraged to work with the knowledge that women experience  
888 many disparities and negative life experiences due to poverty, therefore they are  
889 encouraged to strive to mitigate the experience of poverty and respective social problems  
890 such as homelessness, joblessness, and a lack of education. Working with such an  
891 understanding also calls for engaging from a social justice perspective with women with  
892 SMI, as the idea of social justice emphasizes the need to act for justice on the behalf of  
893 individuals who do not have equitable resources or power due to being marginalized,  
894 such as women with SMI (Constantine, Hage, Kindaichi, & Bryant, 2007). Relatedly, as

895 Vera and Speight (2003) point out, psychologists are recommended to take on diverse  
896 roles rather than staying fastidious to traditional roles. This translates into advocating for  
897 resources, such as financial assistance, housing, education, employment opportunities,  
898 and supported employment. By seeing oneself as a social change agent, psychologists  
899 have the opportunity to extend their reach into communities and affect the sociopolitical  
900 factors that play an impact on the experience of poverty among women with SMI.

901 Psychologists are encouraged to engage with women with SMI around their  
902 employment status, satisfaction with employment, and/or desire for employment.  
903 Psychologists are urged to advocate for and locate employment resources, if this is a  
904 desired goal of the individual. As the *Proficiency in Psychology in the Assessment and*  
905 *Treatment of Serious Mental Illness* (American Psychological Association, 2009)  
906 advocates, Supported Employment has substantial outcome data for its efficacy and is an  
907 approach to finding employment that includes a rapid job search, competitive wages for  
908 jobs, integrated vocational and mental health services, ongoing support once employed,  
909 and the honoring of client choice in occupation. Therefore, connection to opportunities  
910 for Supported Employment may offer important resources. The literature provides  
911 evidence for Supported Employment showing improved employment outcomes across  
912 diverse populations and settings (Becker & Drake, 2003; Bond, et al., 2001; Bond, Drake,  
913 & Becker, 2008; Twamley, Jeste, & Lehman, 2003), which is likely to have multiple  
914 effects on personal well-being.

915 Psychologists are urged to make efforts to understand the educational attainment  
916 of women with SMI, make efforts to support educational endeavors, and locate resources  
917 to engage in such agendas. Additionally, psychologists are encouraged to consider the

918 option of resource connection to such supportive services as supported education  
919 (Nuechterlein et al., 2008). The Recovery to Practice Curriculum (2014) recognizes that  
920 supported education is generally recognized as supportive and helpful. Supported  
921 education aids individuals with SMI in obtaining, continuing, or gaining extra education  
922 and is a collaborative process with a specialist or team. Such programs may help women  
923 with SMI achieve personal learning goals or become successfully employed.

924 Psychologists are encouraged to make efforts to aid in the prevention of  
925 homelessness, mitigate the negative impact of homelessness, and instigate opportunities  
926 that lead to housing when working with women with SMI. The consensus in the field is  
927 that having safe, reasonable housing is one of the best first steps towards recovery  
928 (Housing First), and that providing stable housing decreases homelessness (Recovery to  
929 Practice Curriculum, 2014). Supportive housing integrates case management, support,  
930 psychotherapy, and skills training, as well as other supports for treatment for mental  
931 illness and any dual diagnosis (Padgett, Stanhope, Henwood, & Stefancic, 2011). The  
932 literature also indicates that Housing First models rather than Treatment First models  
933 have better outcomes for reduced substance use, avoiding relapse, and increasing  
934 retention. Additionally, as the literature highlights, the high risk for women with SMI  
935 who experience homelessness, and the associated impact of homelessness, there are far-  
936 reaching implications for psychologists moving out of traditional comfort zones to aid  
937 with this essential need.

938 ***Guideline 9: Psychologists are encouraged to support women in managing family***  
939 ***responsibilities to enhance empowerment within these roles.***

940           **Rationale.** In the last 15-20 years there has been more attention in the literature  
941 highlighting the need to understand experiences of women with SMI who have important  
942 family responsibilities, such as parenting or motherhood. Mowbray, Oyserman, and  
943 Bybee (2000), notable scholars on the topic of women with SMI in parenting roles, have  
944 discussed the long-held bias in the mental health field that women with SMI cannot fill  
945 such important roles as mothering or parenting; they also highlight that their needs or  
946 concerns are different than other women who may experience challenges such as poverty  
947 or urban living. The desire to be in a parenting or mothering role by women with SMI is  
948 increasingly being recognized, though the literature indicates it historically has been seen  
949 as a problematic desire that is pathological, and professionals have held biases that these  
950 women are, as a rule, unfit to be mothers (Montgomery, Tompkins, Forchuk, & French,  
951 2005; Walsh et al., 2002). It is important for mental health professionals to maintain  
952 awareness of any biased views in order to best support women with SMI in their recovery  
953 journey. There is a growing body of research that indicates there is evidence for the  
954 capabilities of these women to fill parenting roles with appropriate support (Nicholson &  
955 Biebel, 2002).

956           The literature indicates that women with SMI have normal fertility rates and have  
957 children at an average or even above average rate (Mowbray, Oysterman, & Bybee,  
958 2000). There are also a significant number of women with SMI that serve as mothers or  
959 in parenting roles of children (approximately 10-65%). Interestingly, 10-15% of women  
960 develop a mental illness postpartum (Dipple et al., 2002; Downey, Coyne, 1990; Joseph  
961 et al., 1999; Mowbray, Oysterman, & Bybee, 2000; Nicholson & Biebel, 2002; Oates,  
962 1988). Additionally, women with SMI are more likely to face parenting as single

963 mothers, experience lower socioeconomic status, begin having children at an earlier life  
964 stage, and are more likely to face family problems and victimization (Belle, 1990;  
965 Downey & Coyne, 1990; Mowbray, Oysermann, Bybee, McFarlane, & Rueda-Ridle,  
966 2001; Nicholson, Sweeney, & Geller, 1998; Olson & Banyard, 1993; Wang &  
967 Goldschmidt, 1994). Challenges that women with SMI face also include inadequate  
968 living circumstances, the effects of mental health symptoms and medication side effects,  
969 the challenges of dealing with stigma, and ever-present fears of having their children  
970 taken away by child protective services (Montgomery, Tompkins, Forchuk, & French,  
971 2005).

972       The fear of having their children taken away or losing custody is a realized  
973 concern, as the literature indicates women with SMI are at increased risk of losing  
974 responsibility for caring for or complete custody of their children, and therefore many  
975 women mask their parenting struggles and mental health issues (Hollingsworth, 2004;  
976 Nicholson, Biebel, Hinden, Henry, & Stier, 2001; Nicholson, Sweeney, & Geller, 1998).  
977 Some studies have reported more African American women experiencing child custody  
978 loss, while other studies indicate more white women lose their children (Lewis,  
979 Giovannoni, & Leake, 1997; Sands, 1995; Zuravin & Greif, 1989). There is evidence of a  
980 greater likelihood to experience child custody loss in the following circumstances: there  
981 are problems with parenting skills, being younger at the birth of the first child, having a  
982 greater number of children, experiencing single parenting, experiencing more personal  
983 distress, unemployment or underemployment, experiencing homelessness, and having  
984 less social support or less social services (Hollingsworth, 2004). Literature does indicate  
985 that children of parents with SMI are more likely to experience foster care, behavior

986 problems, and psychiatric disorders themselves (Ghodsian, Zajicek, & Wolkind, 1984;  
987 Jacobsen, Miller, & Kirkwood, 1997; Mowbray, Oysermann, Bybee, McFarlane, &  
988 Rueda-Riedle, 2001; Oyserman, Benbishty, & Ben Rabi, 1992).

989         However, mothering can be a meaningful process for women with SMI, providing  
990 meaning and personal definition to life (Nicholson & Biebel, 2002; Nicholson, Sweeney,  
991 & Geller, 1998). A qualitative study gives life to this identity process, as the identity of  
992 being a mother is seen as signifying normalcy, security, and responsibility, which are  
993 empowering aspects of parenting and distinct from the experiences women may face with  
994 an SMI (Montgomery, Tompkins, Forchuk, & French, 2005). This study also highlights  
995 that rather than having a traditional, more negative biomedical outlook on the experience  
996 of parenting or motherhood among women with SMI, the mental health field may make  
997 mindful shifts to understand and appreciate the mothering efforts of women with SMI in  
998 the context of their challenges that are related to mental illness, which may aid in  
999 increased support and well-being.

1000         The literature highlights some unique findings that have implications for  
1001 empowerment among women with SMI in their chosen role of parenting or mothering.  
1002 For example, Oyserman and colleagues (2002) found that social support, social stress,  
1003 and financial stress have implications that affect parenting outcomes. These findings  
1004 indicate that social support, adjusted income that is higher, and less stress have positive  
1005 implications for maternal involvement in parenting roles among women with SMI.  
1006 Furthermore, this study found current mental health functioning with fewer symptoms  
1007 has implications for women with SMI being better apt to get social support, which in turn

1008 can impact parenting. Thus, better psychiatric functioning also relates to experiencing  
1009 less stress, both financial and social.

1010       **Application.** Psychologists are encouraged to become more aware of the  
1011 literature on the value of mothering or a parenting role among women with SMI and the  
1012 implications for clinical practice. There is a significant and growing amount of literature  
1013 on this topic that can inform our understanding, bring to light our own biases or  
1014 misassumptions as a profession, and provide a guide to advanced clinical engagement. In  
1015 this process, and as psychologists engage in their areas of expertise, they are encouraged  
1016 to also conduct an intrapersonal process in which they examine their own biases or  
1017 assumptions they have held about the capabilities of women with SMI to engage in  
1018 mothering or a parenting role, while utilizing Sue, Ivey, and Pederson's (1996) model for  
1019 cultural competence. Becoming more cognizant of our own biases or assumptions that we  
1020 may have erroneously held can help psychologists to prevent treatment that is unjust,  
1021 dismissive, marginalizing, stigmatizing, or paternalistic. With this increased awareness,  
1022 psychologists may be better apt to provide clinical services that espouse the general  
1023 principles of the APA Ethics Code (2002) of equality, fairness, and avoidance of biases  
1024 instead of exacerbating experiences such as stigma and marginalization.

1025       As psychologists engage in clinical services with their clients they are also  
1026 encouraged to explore the personal meaning of the parenting or mothering role for each  
1027 individual. Given that these roles might mean something very different per individual, it  
1028 is important to understand the literature, but also interpret that within the context of the  
1029 personal cultural experience and meaning for each woman with SMI. For example, one  
1030 woman may embrace her role as a mother or parent and want to hold fast to those

1031 meanings, build on this part of her life, and find personal value and empowerment from  
1032 such an identity. Another woman may have only experienced more hardship from the role  
1033 of mothering, and may not feel as negatively about the loss of custody. As researchers  
1034 advocate (Mowbray, Oyserman, Bybee, & McFarlane, 2002; Oyserman, Bybee,  
1035 Mowbray, & McFarlane, 2002), psychologists are encouraged to be careful to assess the  
1036 status and current functioning of mothers with SMI, rather than assuming there are  
1037 problems or intervention needs that may not be present.

1038 For those women who fear they are at risk of losing custody of their children or  
1039 have lost custody of their children and this is identified as a particularly challenging or  
1040 painful process, psychologists are encouraged to aid their clients in being able to process  
1041 the meaning of this experience, any difficult emotional reactions, and find appropriate  
1042 social services to support such concerns. The literature highlights that family members  
1043 may reinforce a sick role for mothers with mental illness, overlooking family members or  
1044 women with SMI's own value for input or consultation regarding decision making about  
1045 their children (Nicholson, Sweeney, & Geller, 1998). In this respect, family members  
1046 may undermine the efforts of mothers to balance the demands of managing their mental  
1047 illness and the roles of parenting, which can cause even more difficult dynamics  
1048 (Nicholson, Sweeney, & Geller, 1998). Psychologists are encouraged to explore the  
1049 dynamics between family members or those that may have roles in parenting the children  
1050 of a client. Psychologists may strive to empower the client to serve in the role of mother  
1051 in the capacity she can, and reinforce positive relational and healthy boundary dynamics  
1052 with other parties involved. If a mother has lost custody of her children, but would still

1053 like a role in her children's lives, psychologists are encouraged to explore how that can  
1054 be done and what supports can be incorporated to make that possible.

1055         Psychologists are encouraged to engage their clinical expertise in helping treat  
1056 any mental health symptoms women with SMI are experiencing, as the literature  
1057 indicates current mental health functioning plays a part in parenting capacity (Oyserman,  
1058 Bybee, Mowbray, & McFarlane, 2002). Additionally, psychologists are encouraged to  
1059 utilize the best evidence-based treatments and practices that can be beneficial for women  
1060 with SMI, as suggested by the Recovery to Practice Curriculum (2014). Developing up-  
1061 to-date training and skills in evidence-based practices has the potential to impact  
1062 outcomes. This approach is also very meaningful from a social justice perspective as the  
1063 literature indicates there is a science-to-service gap issue (Drake et al., 2001; Farkas,  
1064 Jansen, & Penk, 2007), meaning that the literature shows there are many evidence-based  
1065 practices for individuals with SMI, but few actually receive those services. It is also  
1066 worth noting that many evidence-based treatments focus only internally and ignore the  
1067 cultural context, which could make a significant difference in how women and diverse  
1068 women experience a practice that is deemed evidence-based by a randomized clinical  
1069 trial.

1070         As the literature indicates women with SMI may be single parenting and  
1071 experiencing less social support (Hollingsworth, 2004), psychologists are encouraged to  
1072 partner with their clients to ascertain levels of social support, interest in increased social  
1073 support, and appropriate avenues for social support. The literature indicates that it may be  
1074 helpful to assess what support individuals do have from family and their capacity to  
1075 parent and engage in treatment (Nicholson, Sweeney, & Geller, 1998). For example, is

1076 there concrete support at times when a mother needs to attend a treatment appointment  
1077 and needs childcare or is their support for actual treatment engagement from family  
1078 members or loved ones in taking medications or for seeing a treating clinician? The  
1079 literature also indicates it may be helpful to provide support to the family in the context  
1080 of supporting parenting/mothering by an individual, while also trying to balance mental  
1081 health needs (Nicholson, Sweeney, & Geller, 1998).

1082 As women with SMI are more likely to experience challenges with housing,  
1083 financial support, and employment (Draine, Salzer, Culhane, & Hadley, 2002; Folsom &  
1084 Jeste, 2002; Perese, 2007), which has likely implications for the capacity for involvement  
1085 in parenting roles, psychologists are encouraged to attend to these potential needs and  
1086 engage in roles as community connectors, advocates, and social change agents to  
1087 empower increased social resources and equity within the community. As the literature  
1088 indicates, parenting under the stress of poverty and social challenges can impact the well-  
1089 being of children and mothers, therefore intervening in this manner is imperative  
1090 (Mowbray, Oyserman, & Bybee, 2000).

1091 ***Guideline 10: Psychologists could work to enhance the peer support network of women***  
1092 ***with serious mental illness to overcome social barriers posed by stigma and mental***  
1093 ***health symptoms.***

1094 **Rationale.** Peer support is defined as when two or more people with  
1095 similar experiences get together to share their experiences, to learn together how to move  
1096 past the difficulties that these experiences have created in their lives, to give each other  
1097 hope, and to support each other as they do the things they want to do and make their lives  
1098 the way they want them to be (Copeland, 2015). The peer support National Practice

1099 Guidelines entail providing peer support on a voluntary basis in a manner that is hope-  
1100 inspiring, open-minded, empathetic, respectful, facilitative of change, honest and direct,  
1101 mutual and reciprocal, equitable in power relations, strengths-based, transparent, and  
1102 person-centered (International Peer Supporters, 2016).

1103 Peer support is an alternative and/or complementary response to medical  
1104 treatment of mental illness. Some posit that peer support in its purest form, solely led and  
1105 received by those who have experienced mental illness, by definition cannot be co-  
1106 located within traditional mental health agencies or systems (Valenstein, 2015). On the  
1107 other hand, health care systems such as Medicaid and the Veterans Health Administration  
1108 have supported the integration of peer support providers as an innovative and effective  
1109 strategy to improve clinical and recovery outcomes for the populations they serve. One  
1110 form of peer support, called Intentional Peer Support, stresses a new way of thinking  
1111 about and inviting transformative relationships. Intentional Peer Support differentiates  
1112 itself from traditional mental health and social services by viewing relationships as an  
1113 equal partnership where both parties learn and grow, not assuming that there is a  
1114 problem, promoting a trauma-informed way of communicating, situates one's life in the  
1115 context of mutually accountable relationships and communities, and encouraging  
1116 enacting what we want rather than focusing on what needs to be stopped or avoided  
1117 (Intentional Peer Support, 2016).

1118 Women with SMI may benefit from encounters with peer support, which aims to  
1119 ameliorate and heal the typical limiting and/or harmful experiences that consumers have  
1120 had with traditional mental health care. For example, these women may have experienced  
1121 feeling inferior in the typical power dynamic between provider and patient. These

1122 individuals may have experienced disempowering and retraumatizing experiences in  
1123 various outpatient, inpatient, and residential treatment settings. Furthermore, women with  
1124 SMI who embody one or more identity dimensions potentially subject to sexism, ableism,  
1125 classism, and racism, may greatly benefit and feel at home in interacting with a peer or  
1126 peers to mirror and empathize with their identity and their life experiences.

1127 ***Application.*** Psychologists are encouraged to become knowledgeable about peer  
1128 support organizations at the national, state, and community levels. They are also urged to  
1129 become knowledgeable about resources and services offered by organizations, such as the  
1130 National Alliance of Mental Illness (NAMI) and The Copeland Center. NAMI offers a 10  
1131 session course, called Peer-to-Peer; local availability of this is searchable through the  
1132 NAMI website. The Copeland Center is an international training organization that  
1133 certifies facilitators of a manualized approach to recovery called Wellness and Recovery  
1134 Action Plan. States and local communities often have peer support services available at  
1135 venues such as a respite centers, recovery centers, and Clubhouses.

1136 Psychologists are also encouraged to consider systems barriers to women with  
1137 SMI as they access healthcare, such as the ability to bring children to appointments at the  
1138 clinic where they receive their care, financial support, or transportation support to get to  
1139 appointments and/or take medications. Psychologists are encouraged to be change agents  
1140 and help think of creative solutions for the delivery of care to support women in their  
1141 diverse experiences. Also, psychologists aspire to become well-versed in the state of the  
1142 research evidence for iterations of peer support, such as peer-to-peer, WRAP, and  
1143 providers and programs geared toward specific issues. Finally, psychologists are  
1144 encouraged to advocate for women with SMI to engage in and perhaps to become

1145 providers of peer support. Given the possible accumulation of experiences that may erode  
1146 the self-knowledge, self-concept, and self-confidence of women with SMI, it is especially  
1147 important that psychologists be supportive in facilitating these individuals' mental health  
1148 recovery and engagement in their communities, as self-defined.

1149 Rogers (2017) reviewed the current evidence base on peer specialists, and found  
1150 that this service appears to be especially useful in enhancing social support and mental  
1151 health and coping, and reducing reliance on traditional mental health providers. Peer  
1152 support appears to offer a unique opportunity for self-disclosure on the part of the peer  
1153 specialist that is instrumental to fomenting the therapeutic alliance via shared lived  
1154 experience. However, Rogers recommended more rigorous research to be conducted in  
1155 this area and more research is needed as to the potential applications to the specific needs  
1156 of women with SMI.

1157 ***Guideline 11: Psychologists strive to address the relationship goals and interests of***  
1158 ***women with serious mental illness to ensure safety and fulfillment.***

1159 ***Rationale.*** Though the majority of people in the U.S. report engagement in a  
1160 significant dating or partner relationship in their adult lives, individuals with SMI have  
1161 greater difficulty having or maintaining sexual partnerships and/or marital relationships  
1162 (Laumman et al., 1994; Wright, Wright, Perry, & Foote-Ardah, 2007). The literature  
1163 indicates that 30-70% of individuals with SMI report being sexually active, with fewer  
1164 reporting a marital or long-term relationship. There are many theoretical explanations for  
1165 this that point to the impact of discrimination, which is associated with stigma from  
1166 mental illness or from physical side effects of medication (Agerbo et al., 2004; Buckley  
1167 et al., 1999; Carey et al., 1999; Carey et al., 2001; Dickerson et al., 2004; Wright, Wright,

1168 Perry, & Foote-Ardah, 2007). Related to societal stigma of mental illness and pulling  
1169 from modified labeling theory (Link, 1987), the literature indicates many people devalue  
1170 individuals with SMI as potential spouses or partners due to the stigma of mental illness,  
1171 with the most potent negative reactions drawn from the idea of entering a marital  
1172 relationship with someone with mental illness (Link et al., 2004).

1173 As Deegan (2001) relates, individuals with SMI experience the need for love,  
1174 intimacy, and companionship just like the general population. However, they may fear  
1175 rejection, withdraw from others in efforts to protect themselves, lack social skills needed  
1176 to attract others, and ultimately choose to avoid relationships or withdraw to avoid  
1177 rejection, which may reduce the likelihood of intimate relationships (Wright, Wright,  
1178 Perry, & Foote-Ardah, 2007).

1179 Wright and colleagues (2007) found that women with SMI are more likely than  
1180 men with SMI to be sexually active, in contrast to the general population, and are also  
1181 more likely to engage in unprotected, higher risk sexual encounters. Those authors also  
1182 found that women with SMI are more likely than men to have concurrent sexual  
1183 relationships. The unique challenges that women with SMI may face are also highlighted  
1184 by the research that indicates 79.4% of these women have experienced physical assault  
1185 by a partner or relative within the previous year (Cascardi, Mueser, DeGiralomo, &  
1186 Murrin, 1996), and are particularly prone to experiencing abuse in sexual relationships  
1187 (Dickerson et al., 2004; Goodman et al., 1997).

1188 ***Application.*** Psychologists are encouraged to explore the relational interests of  
1189 the women with whom they work, who have SMI, and identify what value partner,  
1190 marital, or sexual relationships serve for the individual. Psychologists strive to explore

1191 the supports women have to foster the maintenance of healthy relationships, initiation of  
1192 new relationships that are desired, and ability to have healthy boundaries within  
1193 relationships and/or make empowering choices in relationships that may be abusive. As  
1194 identified needs may come up in the area of requisite supports to pursue personal  
1195 relational goals psychologists are encouraged to provide appropriate psychosocial  
1196 supports or connect individuals to advantageous resources. These could include avenues  
1197 for exploring dating relationships, social skills training, therapeutic interventions or  
1198 resources for intimate partner violence, and referrals to appropriate healthcare, which  
1199 may address goals related to sexual activity and protection. Furthermore, psychologists  
1200 are encouraged to explore in therapy the role of stigma on the relational goals of women  
1201 with SMI and introduce mechanisms to mitigate the impact of stigma. For example, a  
1202 psychologist may explore the impact of internalized oppression on a woman's belief that  
1203 others may not be interested in her as a romantic or sexual partner due to the fact that she  
1204 has an SMI.

1205 From an advocacy perspective, psychologists are encouraged to advocate for  
1206 women with SMI that may be experiencing challenges within our mental health systems  
1207 due to policies that marginalize the right to have romantic and/or sexual relationships. For  
1208 instance, psychologists are encouraged to explore what policies inpatient psychiatric units  
1209 have on the rights for sexual expression and offer support to foster romantic and/or sexual  
1210 partnerships (Deegan, 2001). Psychologists are encouraged to look at this issue from a  
1211 social justice perspective as many mental health systems ignore or deny the right for  
1212 individuals with SMI to pursue such relationships. Additionally, psychologists strive to  
1213 explore how community – or outpatient programs are organized to be inclusive of women

1214 who identify with different sexual orientations, gender identities, and gender expressions.  
1215 Along these lines, psychologists are encouraged to integrate and educate themselves with  
1216 other guidelines, such as the transgender guidelines, which may further advance practice.  
1217 Psychologists are also encouraged to educate medical personnel, public service  
1218 professionals in law enforcement and criminal justice, and other community members  
1219 about socially just ways to work with women with SMI.

1220 Psychologists aspire to provide a crucially safe therapeutic space to  
1221 psychologically process dissatisfaction or challenges in relationships and especially in the  
1222 realm of experiences of violence/abuse. They are encouraged to assess issues of safety  
1223 and empower women with SMI with tools that may enhance their feeling of safety,  
1224 autonomy, self-determination, and choice. Additionally, in the face of experiences of  
1225 sexual and/or physical abuse psychologists aspire to acknowledge the impact of trauma  
1226 on the lives of women with SMI and either provide, or refer to, appropriate psychological  
1227 treatment for these concerns, if indicated.

1228 ***Guideline 12: Psychologists may conceptualize substance use treatment as an equal***  
1229 ***component of the mental health care of women with serious mental illness, and provide***  
1230 ***treatment for dual diagnoses.***

1231 **Rationale.** The literature indicates that substance use disorders are the most  
1232 common and significant co-occurring experience for people with SMI (Drake, Mueser,  
1233 Brunette, & McHugo, 2004), with lifetime prevalence rates approximated at 50% among  
1234 all individuals with the experience of a SMI (from a study of over 20,000 people in the  
1235 U.S.) (Regier et al., 1990). Many other studies report similarly high rates of the co-  
1236 occurrence of substance use and SMI (Drake & Wallach, 2000; Mueser et al., 2000). The

1237 importance of this concern is multi-fold, as the co-occurrence of SMI and substance use  
1238 disorders is associated with many significant challenges including, but not limited to  
1239 higher rates of homelessness (Caton et al., 1994), victimization (Goodman, Rosenberg,  
1240 Mueser, & Drake, 1997), worsening symptoms of depression and increased risk of  
1241 suicide (Meyer, Baborm & Hesselrock, 1988; Torrey, Drake, & Bartels, 1996), and  
1242 increased family burden, interpersonal conflict, and financial problems (Mueser,  
1243 Noordsy, Drake, Fox, 2003).

1244         There is also research that indicates that women who experience mental illness are  
1245 more vulnerable than men to the intoxicating and addictive components of drugs, which  
1246 may have biological origins (Gearon & Bellack, 1999). Furthermore, based on evidence  
1247 indicating that women become more easily intoxicated than men, they also develop  
1248 substance use disorders sooner than men, making them particularly vulnerable (Lex,  
1249 1995; Shuckit et al., 1995). A study on gender difference in the experience of  
1250 schizophrenia provided evidence that the more benign course and presentation of illness  
1251 typically seen in women with schizophrenia, as compared to men, disappears when  
1252 women abuse substances (Gearon & Bellack, 2000). The combination of having these co-  
1253 occurring challenges also significantly raises the risk for trauma exposure and resultant  
1254 negative outcomes for women (Gearon, Kaltman, Brown, & Bellack, 2003). In fact, large  
1255 scale studies indicate that the rates of physical and sexual abuse in women with SMI that  
1256 are abusing drugs are notably higher than the rates seen among women in the general  
1257 population that are not abusing drugs and/or experiencing a SMI (Dansky et al., 1996;  
1258 Cottler, Nishith, & Compton, 2001). One such study indicates a very high rate of physical  
1259 abuse (81%) and revictimization in women with a co-occurring SMI and substance use

1260 disorder (Gearon, Kaltman, Brown, & Bellack, 2003). Additionally, this same study  
1261 provided evidence that prevalence rates of current PTSD (46%) are much higher than  
1262 previously reported for women with co-occurring SMI and substance use disorders  
1263 (Gearon, Kaltman, Brown, & Bellack, 2003). Clearly, this has serious implications for the  
1264 impact of the dual experience of these two challenging issues among women.

1265       **Application.** Psychologists are encouraged to fully assess women with SMI for  
1266 the presence or warning signs of a substance use disorder, given the vulnerability to  
1267 developing substance use problems and the impact of the co-occurring SMI. The  
1268 literature indicates that women with some SMI diagnoses, such as schizophrenia and  
1269 schizoaffective disorder, are less represented than men in substance use treatment  
1270 programs. Access to care and advocacy for the right to evidence-based substance use  
1271 prevention and intervention may be seen as a social justice issue (Alexander, 1996;  
1272 Gearon & Bellack, 1999). Along these lines, a thorough review of the best modalities of  
1273 treatment for the co-occurrence of substance use disorders and SMI recommends that  
1274 effective treatments are integrated dual diagnosis treatment (IDDT), which address both  
1275 concerns simultaneously, rather than offering treatment in silos (Dixon et al., 2009;  
1276 Drake, Mueser, Brunette, & McHugo, 2004). In addition to access to evidence-based  
1277 practices, women with SMI and substance use disorders ideally may be afforded the  
1278 opportunity to have effective components of treatment, such as individualized treatment  
1279 that addresses personal factors, engagement in treatment, relapse prevention, stages of  
1280 motivation, and the ability to develop skills and supports (Dixon et al., 2009; Drake,  
1281 Mueser, Brunette, & McHugo, 2004). Consideration for integrated residential treatment,  
1282 especially long-term, of one year or more, may be considered for those women who do

1283 not respond to outpatient treatment, as the evidence is better for such treatment modalities  
1284 (Drake, Mueser, Brunette, & McHugo, 2004).

1285         Given the multitude of more significant problems with the duality of the  
1286 experience of SMI and substance use disorders, and the particular vulnerability for  
1287 women for increased trauma exposure and PTSD (Gearon, Kaltman, Brown, & Bellack,  
1288 2003), psychologists are encouraged to regularly screen for recent victimization among  
1289 women with SMI and substance use disorders (Goodman et al., 2001). This investigation  
1290 is recommended to be part of the intake assessment and be done in an ongoing manner,  
1291 including specific and behaviorally anchored questions that may elucidate whether  
1292 women are experiencing coercive sexual or physical experiences or threats, which  
1293 impinge on their feeling of safety (Goodman et al., 2001). If there is an experience of  
1294 trauma psychologists are encouraged to also treat that aspect of their current presentation  
1295 and need for safety, while simultaneously addressing the concerns of their experience of  
1296 SMI and substance use. For women with past or current histories of trauma, the  
1297 treatments offered preferably are trauma-informed, as well as the systems in which they  
1298 are offered.

1299 ***Guideline 13: Psychologists strive to focus on the safety of women with serious mental***  
1300 ***illness to reduce the risk of suicidality and enhance coping strategies.***

1301         Among those with SMI, risk of suicide varies from 8.5 (schizophrenia) to 15  
1302 (bipolar disorders) to 20 (major depression) times the expected rate, calculated by a  
1303 standardized mortality ratio (Harris & Barraclough, 1997). Moreover, the presence of  
1304 eating disorders, which are generally not considered a SMI, but which increase suicide  
1305 risk, may be a pertinent consideration during provision of clinical care, given their

1306 prevalence among women. The risk of suicide for eating disorders has been found to be  
1307 23 times the expected rate (Harris & Barraclough, 1997).

1308         There are some additional issues to consider with regard to suicide and women  
1309 with SMI. One is the co-morbidity between SMI and Borderline Personality Disorder  
1310 (BPD). Between 40% and 65% of individuals who commit suicide meet criteria for a  
1311 personality disorder, the most common of which is BPD. A Borderline Personality  
1312 Disorder diagnosis co-occurs in 46-56% of women diagnosed with PTSD, and in 10-20%  
1313 of women diagnosed with bipolar disorder (McGlashan, 2000). BPD is more commonly  
1314 diagnosed and treated in women versus men (approximately 70% versus 30%,  
1315 respectively) (Lieb, Zanarini, Schmahl, Linehan, Bohus, 2004). Estimates of the mortality  
1316 rate from suicide of those with BPD are as high as 10% (Paris & Zweig-Frank, 2001). For  
1317 individuals with BPD and suicidality who enter treatment, it is suggested that the first  
1318 priority is to decrease suicidal behaviors by increasing behavioral control, during which  
1319 the severity of suicidality may be actively and consistently monitored.

1320         There is little data that pharmacotherapy reduces risk of suicide or attempted  
1321 suicide, and pharmacotherapy or hospitalization may not be effective for women with  
1322 BPD (Soloff, 2000). Rather, results from randomized controlled trials of Dialectical  
1323 Behavioral Therapy (DBT), a form of structured outpatient psychotherapy that includes  
1324 skill building in emotion regulation, mindfulness, interpersonal effectiveness, and distress  
1325 tolerance, as well as intensive psychotherapy with coaching calls, indicate that an  
1326 aggressive, outpatient treatment, which rarely hospitalizes, shows lower rates of suicide  
1327 attempts than standard treatment (i.e., emergency services and inpatient treatment) (for a  
1328 review, Linehan, 2010). Thus, DBT reduces risk of suicidal and self-harm behaviors.

1329 Another relevant issue for women with SMI is perinatal suicide in mothers.  
1330 Female suicide, versus male suicide, is less associated with unemployment, adversity,  
1331 single status, and divorce (Oates, 2003). Suicide is the leading cause of maternal death  
1332 based on a national U.K. report (Oates, 2003). Maternal deaths due to psychiatric causes  
1333 such as suicide, substance use, and homicide have been measured at 12%, with suicide  
1334 accounting for the majority, at 10%. Among these deaths by suicide, 68% were related to  
1335 an SMI such as psychosis or severe depression. That epidemiological report indicated  
1336 that the majority of maternal suicides were by violent means, such as by hanging or  
1337 jumping, rather than from medication overdose. However, in contrast to previous studies  
1338 on gender differences, regarding the method of suicide, women were more likely to die  
1339 by non-violent means such as overdose.

1340 Remarkably, in the cases of maternal suicide, it was rare that mental health or  
1341 maternity professionals knew of the risk of suicide, and to an even lesser extent had  
1342 implemented behavioral management plans, despite a previous history of SMI or post-  
1343 partum depression among these mothers. Of the maternal deaths by suicide, 46% had  
1344 documented mental health problems and were in contact with mental health services  
1345 (Oates, 2003). Furthermore, oftentimes even when previous postpartum psychiatric  
1346 history was recorded, postpartum depression was the diagnosis on record even when  
1347 postpartum psychosis may have been more accurate and indicative that more intensive  
1348 interventions may have been warranted.

1349 **Application.** Psychologists are encouraged to know the higher rates of suicide  
1350 among clinical disorders such as major depression, bipolar disorder, schizophrenia, and  
1351 eating disorders. Furthermore, particular attention could be paid to outpatient outreach,

1352 evidence-based interventions, and psychiatric screening and behavioral management for  
1353 BPD, PTSD, and maternal postpartum depression and psychosis. It is vital to integrate  
1354 sound professional judgment with gender-specific knowledge into decision-making  
1355 regarding suicidality. Increasing this awareness could potentially help many individuals  
1356 to get the appropriate level of services to meet their needs. Additionally, as the  
1357 experience of pregnancy is a potentially distressing and at-risk time in life, psychologists  
1358 and others providing psychological services to women with SMI could try to connect  
1359 expectant mothers to appropriate supports which could potentially mitigate the likelihood  
1360 of postpartum depression and psychosis, and offer resources that could promote  
1361 engagement in parenting, while also receiving supports that more directly facilitates  
1362 women's own mental health recovery.

There are many terms used throughout these guidelines, which may be used often in specialized work with women with SMI but there may be some who read the guidelines that may not understand the terms. Therefore, the following definitions are offered as a way to ensure that those reading the document understand the use of the terms that are being conveyed.

**Culturally Responsive:** an approach that aims to not only be sensitive or aware but be responsive to the element of culture and the unique experience of the client. From this perspective a few goals from the literature share that a culturally responsive approach attempts to engage in some of the following ways: not only be culturally-informed but provide person-specific assessment of the presenting issue, engage in education regarding specific cultural norms and consult the literature for culture-specific treatment techniques, ensure adequate and effective training has occurred for cross-cultural competency, explore client's perspective on seeking treatment and of the therapeutic relationship, incorporate client's strengths and resources into treatment, and use technique-specific cultural modifications as appropriate (Asnaani & Hofmann, 2012).

**Dynamic Sizing:** understanding when to generalize and when to individualize a client's particular experiences based on various cultural contexts and multiple identities (Sue, 1998).

1993 **Empowerment Approach:** an approach, which allows individuals, families, and  
1994 communities to gain influence over sociopolitical factors that affect their health and well-  
1995 being (Worell & Remer, 2003).

1996 **Intersectionality:** is a theory that may enhance understanding how various social  
1997 identities contribute to compounded levels of stigma, oppression, and privilege  
1998 (Crenshaw, 1993). Intersectionality demonstrates how constructs like race and class are  
1999 not separate processes but intersecting social hierarchies that determine access to power  
2000 (Collins, 2000).

2001 **People-first Language:** use of language that shows respect by referring to an individual  
2002 first by their name and then by their disability when needed such as “person with serious  
2003 mental illness.” This approach demonstrates respect for the individual and that they are  
2004 inherently a person first with capabilities, rather than naming them by what they are  
2005 perceived to have as a disability (Blaska, 1993).

2006 **Recovery:** is a shift away from traditional uses of the word “recovery”, such as the  
2007 absence of symptoms or substance use, but focuses on hope, self-determination,  
2008 empowerment, and person-centered care (SAMSHA, 2012). The recovery-oriented care  
2009 movement came out of the consumer movement in the 1960s and 1970s in which  
2010 individuals in hospitals fought for their rights and the capacity to live autonomously in  
2011 the community and to have a life that was more than just being a patient (Davidson,  
2012 Tondora, Lawless, O’Connell, & Rowe, 2009). It means recovery occurs despite  
2013 symptoms recurring or being in the hospital again. This perspective focuses on the rights  
2014 of those with mental illness to be empowered, have a voice in their mental health  
2015 experience, and ultimately live lives of meaning beyond the effects of mental illness. This

2016 perspective calls awareness to the reality that the experience of those with mental illness  
2017 was as much about the sociopolitical experience of stigma, marginalization, and  
2018 discrimination as it was about mental illness.

2019 **Recovery-oriented Care:** a systems approach to mental health care that looks at how to  
2020 implement recovery oriented values and transformation so that mental health systems can  
2021 partner with those in their recovery journey (Davidson et al., 2009).

2022 **Serious Mental Illness (SMI):** refers to major mental health disorders that lead to  
2023 serious impairment in at least one area of functioning, including social,  
2024 academic/occupational, and daily living activities (Kessler et al., 2003; Substance Abuse  
2025 and Mental Health Services Administration (SAMHSA), 2017). SMI typically includes  
2026 bipolar disorder, schizophrenia spectrum disorders, severe depression, and posttraumatic  
2027 stress disorder (PTSD).

2028 **Stigma:** “the threats of diminished self-esteem and of public identification when labeled  
2029 “mentally ill”” (Corrigan, p. 614, 2004).

2030 **Trauma-informed Care:** the provision of mental health services that take in to account  
2031 the understanding of the impact of the interpersonal violence and victimization on an  
2032 individual’s life and development (Fallot & Harris, 2001). This perspective has multiple  
2033 goals but they include such perspectives as offering choice, trustworthiness,  
2034 empowerment, maximizing control, and providing a recovery process.

**Appendix B**

2040

**History of the Development of the Guidelines**

2041

The aims of the Task Force on Women with Serious Mental Illness in Division 35

2042

were to represent and advocate for the needs of women who experience SMI from a

2043

multicultural feminist perspective. The task force was compiled of several feminist

2044

psychologists specializing in working with individuals with SMI who were concerned

2045

about the dearth of formal attention and activism that was being pursued to represent this

2046

group of women.

2047

The feminist rationale for developing the task force was multifold. First, the group

2048

reflected on the fact that there is a significant amount of women that experience SMI

2049

(SAMHSA, 2003). Secondly, women with SMI frequently experience other oppressive

2050

experiences putting them at disproportionate risk of unique challenges (American

2051

Psychological Association, 2009; Bassuk, Weinreb, Buckner, Brown, Saloman, &

2052

Bassuk, 1996; Goodman, Dutton, & Harris, 1995; Roberton, 1996). Furthermore, this

2053

group was concerned that women of other minority social identities who experience SMI

2054

may endure an even greater experience of oppression and marginalization (Carr, Greene,

2055

& Ponce, 2015; Szymanski & Moffitt, 2012). As Division 35 seeks to be a leader in the

2056

field of psychology in advocacy for the rights of all women, the Task Force suggested

2057

that the multicultural feminist movement needed to become stronger in representing and

2058

advocating for the needs and rights of all women who experience SMI. Initiatives of the

2059

group included presentations at national psychological meetings to represent the unique

2060

needs of women with SMI, larger efforts to make contributions to the psychological

2061

literature on women with SMI, and the development of these *Guidelines for*

2062 *Psychological Practice with Women with Serious Mental Illness*. Division 35 was  
2063 supportive of these initiatives and voted to transition the Task Force into a Committee on  
2064 Women with Serious Mental Illness in January 2016 at their Mid-Winter Annual Meeting  
2065 of the Executive Committee of Division 35, in order to provide a mechanism to continue  
2066 the work of the original Task Force.

2067         The core group began its initial focus on the development of Guidelines in 2015,  
2068 including discussions with representatives from APA regarding guideline development  
2069 and a review of the literature. The co-chairs of the Committee and Task Force, Erika Carr  
2070 (Lead Co-Chair) and Lauren Mizock, led the charge to develop guidelines joined by  
2071 group member Shihwe Wang. Other psychologists were later assembled to provide  
2072 additional edits and review of the initial draft that the core group developed. The second  
2073 tier of psychologists, that joined the working group, at the end of 2017 and beginning of  
2074 2018, to edit the draft were included due to the following specializations: psychological  
2075 guideline development, women's mental health, SMI, women with SMI, and  
2076 multicultural feminism. The core group initially met quarterly over conference calls in  
2077 order to begin to develop the guidelines. The core group began to meet monthly over  
2078 conference calls during 2016, and specific writing deadlines were assigned and feedback  
2079 shared on the writing process. After an initial rough draft of the guidelines were  
2080 developed the Lead co-chair, Erika Carr, provided a thorough edit and then next the other  
2081 co-chair, Lauren Mizock, made an edit of the guidelines, and then the draft was edited a  
2082 second time by Erika Carr, as well as reviewed by Shihwe Wang. Congruently the core  
2083 group next provided another edit and discussion to address any outlying issues that  
2084 remained. Other stakeholders and experts in psychological practice with women with

2085 SMI and in women's mental health then provided additional edits to the guidelines. These  
2086 psychologists included: (Marcia Hunt, Stephanie Lynam, Meaghan Stacy, Pamela Remer,  
2087 and Viviana Padilla-Martinez). After their edit, the core group went back and provided  
2088 additional revisions based on the suggestions of those who edited the core group's draft  
2089 of the guidelines.
